

Scratch 1.4	Java	Python
<p>In Scratch an assignment statement binds a name to an object; objects can be of any type — in short, Scratch is dynamically typed and performs auto-boxing as necessary.</p> 	<p>In Java, all variable names (along with their types) must be explicitly declared. Attempting to assign an object of the wrong type to a variable name triggers a type exception. That's what it means to say that Java is a statically typed language.</p> <p>Java container objects (e.g. Vector and ArrayList) hold objects of the generic type Object, but cannot hold primitives such as int. To store an int in a Vector, you must first convert the int to an Integer. When you retrieve an object from a container, it doesn't remember its type, and must be explicitly cast to the desired type.</p> <pre>int age = 26;</pre>	<p>In Python, you never declare anything. An assignment statement binds a name to an object, and the object can be of any type. If a name is assigned to an object of one type, it may later be assigned to an object of a different type. That's what it means to say that Python is a dynamically typed language.</p> <p>Python container objects (e.g. lists and dictionaries) can hold objects of any type, including numbers and lists. When you retrieve an object from a container, it remembers its type, so no casting is required.</p> <pre>age = 26</pre>
	<pre>public class HelloWorld { public static void main (String[] args) { System.out.println("Hello, world!"); } }</pre>	<pre>print "Hello, world!" ----- print("Hello, world!") # Python version 3</pre>
	<pre>// print the integers from 1 to 9 for (int i = 1; i < 10; i++) { System.out.println(i); }</pre> <p><i>Note: In Java a single line block does not require braces, so the following is identical to above</i></p> <pre>for (int i = 1; i < 10; i++) System.out.println(i);</pre>	<pre># print the integers from 1 to 9 for i in range(1,10): print i</pre>
	<pre>if (a > b) { a = b; b = c; }</pre>	<pre>if a > b : a = b b = c</pre>
	<pre>import java.util.Scanner; ... Scanner input = new Scanner(System.in); System.out.print("Enter age: "); int age = input.nextInt(); ...</pre>	<pre>age = input("Enter age: ")</pre>
 <p>Note: In all cases 1.0/3.0 = 0.33333333...</p>	<pre>System.out.println(1/3); 0</pre>	<pre>Python 2.7.x: >>> 1/3 0 Python 3.6.x: >>> 1/3 0.3333333333333333</pre>

For the Java and Python comparison, many of the examples were taken from:

<https://pythonconquerstheuniverse.wordpress.com/2009/10/03/python-java-a-side-by-side-comparison/>

Notes:

1. Types
 - a. In Scratch variable types are dynamic and automatic, including conversion as necessary
 - b. In Java variables are statically "typed" in most cases; conversion must be explicitly performed by the programmer
 - c. In Python variables are dynamically typed, as in Scratch; however, conversion (via casting) is necessary at times
2. Blocks
 - a. In Scratch a block is identified by a construct
 - b. In Java a block is defined by braces
 - c. In Python a block is indented
3. Of course these are just the basics; lists, graphics, methods, events, timers, messaging, and more are also supported
 - a. What are lists, graphics, methods, events, timers, messaging and more?

Take CSC 121 and 123 to find out...
